ABSTRACT

Coupled decompositions of multiple tensors are fundamental tools for multi-set data fusion. In this paper, we introduce a coupled version of the rank-(Lm, Ln, ·) block term decomposition (BTD), applicable to joint independent subspace analysis. We propose two algorithms for its computation based on a coupled block simultaneous generalized Schur decomposition scheme. Numerical results are given to show the performance of the proposed algorithms.

Index Terms — Tensor, block term decomposition, coupled tensor decomposition, multi-set data fusion

1. INTRODUCTION

In the past decade, the block term decomposition (BTD) has attracted increased attention in various signal processing applications. In comparison to the well-known canonical polyadic decomposition (CPD) that writes a tensor as the sum of a minimal number of rank-1 terms, BTD decomposes a tensor into a set of terms of low multilinear rank, which is more flexible and better adapted to applications where the signals are multidimensional. Uniqueness and algorithms for various types of BTD were studied in [1-4] and applications in signal processing were given to show the performance of the proposed algorithms.

Recently, coupled tensor decompositions have been studied in the context of multi-set data fusion, which assumes some links or shared factor matrices among target tensors. They are mainly extensions of CPD to multi-set cases, including the works in [11-20] and the references therein. In addition, the coupled rank-(Lm, Ln, ·) BTD was studied in [15, 16]. Structured data fusion (SDF) was presented in [21] as a flexible framework for coupled and/or structured decompositions. The above works have shown that the coupled decomposition is able to both improve the accuracy and relax the identifiability condition compared with the decomposition of a single tensor.

In this paper, we combine the concepts of coupling and BTD, and introduce a particular coupled rank-(Lm, Ln, ·) BTD. We will show that the particular multi-set data fusion problem of joint independent subspace analysis (J-ISA) can be turned into a coupled rank-(Lm, Ln, ·) BTD. We present two algorithms for the coupled block version of so-called simultaneous generalized Schur decomposition scheme (SGSD, [22-24]). SGSD involves only unitary factors. It has found use in the analytical constant modulus algorithm [22], in the computation of CPD [23], in numerically stable representations of ill-posed CPD problems [24], etc. We here limit ourselves to the overdetermined case. The more challenging under-determined coupled rank-(Lm, Ln, ·) BTD will be addressed in the future.

Notation and definitions: vectors, matrices and tensors are denoted by lowercase boldface, uppercase boldface and uppercase calligraphic letters, respectively. The rth column vector and the (i, j)th entry of $A$ are denoted by $a_r$ and $a_{ij}$, respectively. Symbols ‘⊙’, ‘⊗’, ‘⊙∗’, ‘⊙◦’ and ‘⊙∋’ denote the Kronecker product, block-wise Khatri-Rao product, mode-$n$ product, and outer product, respectively, defined as:

\[
A \otimes B \triangleq \begin{bmatrix} a_1 B & a_2 B & \cdots \\ a_n B & a_{n+1} B & \cdots \\ \vdots & \vdots & \ddots \\ \end{bmatrix}, \quad A \odot B \triangleq [A \otimes B, \cdots, A \otimes B],
\]

\[
(T \times G)_{l_1 \cdots l_d, l_{d+1} \cdots l_D} \triangleq \sum_{i_1=1}^{l_1} \cdots \sum_{i_d=1}^{l_d} s_{i_1 \cdots i_d} (a \odot b \circ c)_{i_1 \cdots i_d} \triangleq a_{i_1 \cdots i_d}.
\]
In the above definitions, we assume $A \triangleq \{A_1, \ldots, A_n\}$ and $B \triangleq \{B_1, \ldots, B_n\}$ for the block-wise Khatri-Rao product. For the mode-$n$ product we assume that the $n$th dimension of $T$ is equal to the number of columns of $G$. We denote the identity matrix and the all-zero matrix as $I_m \in \mathbb{C}^{m \times m}$ and $\theta_{m \times n} \in \mathbb{C}^{m \times n}$, respectively. Transpose, conjugate, conjugated transpose, Moore-Penrose pseudo inverse, and Frobenius norm are denoted as $(\cdot)^T$, $(\cdot)^\dagger$, $(\cdot)^F$, $(\cdot)^\dagger$, $\|\cdot\|_F$, respectively. Mathematical expectation is denoted as $E\{\cdot\}$. MATLAB notations will be used to denote submatrices of a tensor. For instance, we use $T_{i(\cdot), j(\cdot)}$ to denote the frontal slice of a tensor by fixing the third index to $k$.

For a given matrix $T \in \mathbb{C}^{l \times k}$, vec$(T) \in \mathbb{C}^{l \times k}$ denotes column-wise vectorization of $T$ and unvec$(\cdot)$ performs the inverse. For a third-order tensor $T \in \mathbb{C}^{R \times S \times K}$, notations $T_{(i,j),k} \in \mathbb{C}^{R \times S}$, $T_{(i),j,k} \in \mathbb{C}^{R \times K}$, $T_{i,j,(k)} \in \mathbb{C}^{S \times K}$ denote three types of matricization, defined by:

$$T_{(i,j,k)} = \left( T_{(i,j),k} \right)_{i,j,k} = \left( T_{(i),j,k} \right)_{i,j,k} = \left( T_{i,j,(k)} \right)_{i,j,k} = t_{i,j,k}.$$

The mode-$n$ vectors of $T$ are obtained by fixing all but the $n$th index of $T$. The mode-$n$ rank of $T$ is defined as the dimension of the subspace spanned by the mode-$n$ vectors. It is easy to understand that the mode-1, mode-2, and mode-3 rank of $T$ is equal to the rank of $T_{(i,j),k}$, $T_{(i),j,k}$, and $T_{i,j,(k)}$, respectively.

Third-order tensors with mode-1 and mode-2 rank equal to $L_1$, $L_2$, respectively, are said to have multilinear rank-$(L_1, L_2)$, and third-order tensors with mode-1, mode-2, and mode-3 rank equal to $L_1$, $L_2$, $L_3$, without rank constraint in the third mode, are said to have multilinear rank-$(L_1, L_2, L_3)$. Rank-$(1,1,1)$ terms simply correspond to rank-1 terms.

### 2. PROBLEM FORMULATION

In this paper, we consider the following coupled rank-$(L_m, L_n)$ BTD of a set of tensors $T^{(m,n)} \in \mathbb{C}^{I_{m} \times I_{n} \times K}$:

$$T^{(m,n)} = \sum_{s} C^{(m,n)}_s \otimes A^{(m)}_s \otimes A^{(n)}_s,$$

where $C^{(m,n)}_s \in \mathbb{C}^{I_{m} \times I_{n} \times K}$ has mode-1 rank equal to $L_m$ and mode-2 rank equal to $L_n$, and $A^{(m)}_s$ is the latent source vector at time instant $t$, and $A^{(n)}_s \in \mathbb{C}^{R \times K}$ denotes the mixing matrix of the $s$th dataset. In addition, each tensor $T^{(m,n)}$ is coupled with $T^{(m,n)}$ in the first mode by rank factor matrix $A^{(m)}$ and at the same time coupled with $T^{(m,n)}$ in the second mode by $A^{(n)}$. $m' \neq m$, $n' \neq n$. This double coupling structure is illustrated in Fig. 2. The matrix representation of (1) is given by:

$$T^{(m,n)}_{i(\cdot), j(\cdot), k(\cdot)} = (A^{(m)} \circ A^{(n)} \circ C^{(m,n)})_{i(\cdot), j(\cdot), k(\cdot)},$$

where $C^{(m,n)} \in \mathbb{C}^{I_{m} \times I_{n} \times K}$ is the block-diagonal matrix with blocks of size $L_m \times L_n$, containing the $r$th frontal slice of $C^{(m,n)}$ as the $r$th block on its main diagonal.

Note that in (1) we can arbitrarily permute the terms if it is done consistently for all tensors involved. We can also post-multiply $A^{(m)}$ and $A^{(n)}$ by non-singular matrices $F^{(m)}_s \in \mathbb{C}^{I_{m} \times L_m}$ and $F^{(n)}_s \in \mathbb{C}^{I_{n} \times L_n}$, provided that $C^{(m,n)}_s$ is replaced by $C^{(m,n)}_s \\ F^{(m)}_s \times F^{(n)}_s$ for all values of $m$ and $n$. The goal of coupled rank-$(L_m, L_n)$ BTD is then to solve (1) up to these trivial indeterminacies.

![Fig. 1](image1.png)

**Fig. 1.** The rank-$\text{(Lm, Ln)}$ BTD writes each target tensor $T^{(m,n)}$ as the sum of multiple block terms of low multilinear rank.

![Fig. 2](image2.png)

**Fig. 2.** The double coupling structure. The target tensors are placed at different nodes of a grid according to their indices. Each tensor is coupled with tensors along two modes by two factor matrices.

Next we explain how the coupled rank-$(L_m, L_n)$ BTD (1) is related to the J-ISA problem [25]. The multi-set data model for J-ISA is formulated as:

$$x^{(m)}(t) = A_s^{(m)} s^{(m)}(t) + \sum_{s'} A^{(m)}_s x^{(m)}(t),$$

where $x^{(m)}(t) \in \mathbb{C}^{I_{m}}$ denotes the observed mixture, and $s^{(m)}(t) \in \mathbb{C}^{R}$ is the latent source vector at time instant $t$, and $A^{(m)} \in \mathbb{C}^{R \times L_{m}}$ denotes the mixing matrix of the $s$th dataset. We partition the source vector $s^{(m)}(t)$ into $R$ sub-vectors $[s^{(m)}_1(t), ..., s^{(m)}_R(t)] \in \mathbb{C}^{R \times K}$, with each sub-vector $s^{(m)}_r(t)$ representing a group of $L_m$ sources. In addition we partition the mixing matrix $[A_1^{(m)}, ..., A_R^{(m)}] \in \mathbb{C}^{R \times L_{m}}$ as $A^{(m)} \in \mathbb{C}^{R \times L_{m}}$ the sub-matrix of $A^{(m)}$ associated with $s^{(m)}_r(t)$.

We make the following assumptions: 1) each sub-vector $s^{(m)}_r(t)$ contains $L_m$ dependent sources; 2) $s^{(m)}_r(t)$ and $s^{(m)}_s(t)$ are independent for $r \neq s$ and dependent for $r = s$ regardless of the values of $m$ and $m'$; 3) the sources are temporally non-stationary with zero mean and unit variance.

We calculate the cross-covariance tensor as follows:

$$T^{(m,n)}_{i(\cdot), j(\cdot), k(\cdot)} = E\{x^{(m)}(k) [x^{(n)}(k)]^T\} = A^{(m)}_s \Sigma^{(m,n)}_s A^{(n)}_s,$$

where $T^{(m,n)} \in \mathbb{C}^{I_{m} \times I_{n} \times K}$, $1 \leq m, n \leq M, K$ denotes the number of time-frames for which such a cross-covariance is computed. The matrix $\Sigma^{(m,n)}_s \in \mathbb{C}^{I_{m} \times I_{n} \times K}$, with blocks of size $L_m \times L_n$, under the above assumptions. Comparing (5) and (3), we can see that the J-ISA data model has been converted to a coupled rank-$(L_m, L_n)$ BTD formulation by using second-order statistics.
3. ALGORITHMS

We limit ourselves to the overdetermined case where $A^{(m)}$ and $C^{(m,n)}$ in (2) are assumed to have full column rank for all the values of $m,n$, and propose two algorithms for the computation of coupled rank-$\langle L_m, L_n, \cdots \rangle$ BTD, which extend the SGSD scheme to the coupled block case.

3.1. Coupled Block SGSD

The goal of coupled rank-$\langle L_m, L_n, \cdots \rangle$ BTD is to find $A^{(m)}$, $A^{(n)}$ and $\Sigma^{(m,n)}$ that minimize the following function:

$$\eta(\Omega) = \sum_{m,n=1}^{M} \sum_{l=1}^{K} \| Q^{(m)}(\omega) T^{(n)}(\omega) Z^{(n)} - F^{(m,n)}(\omega) \|^2,$$

where $\Omega = \{A^{(m)}, \Sigma^{(m,n)}, m,n = 1,...,M, k=1,...,K\}$ denotes the set containing all the arguments. We let $A^{(m)}$ and $Z^{(n)}$ be a block QR decomposition of $A^{(m)}$ and $A^{(n)}$ be a block $ZL$ decomposition of $A^{(n)}$, where $Q^{(m)} \in \mathbb{C}^{m\times mn}$, $Z^{(n)} \in \mathbb{C}^{n\times nn}$ are unitary matrices, and $R^{(m)} \in \mathbb{C}^{mn\times mn}$, $L^{(n)} \in \mathbb{C}^{nn\times nn}$ are defined as:

$$R^{(m)} = \begin{bmatrix} R^{(m)}_1 & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}, \quad L^{(n)} = \begin{bmatrix} L^{(n)}_1 \mathbf{0} \\ \mathbf{0} \mathbf{0} \end{bmatrix},$$

where $R^{(m)}_1 \in \mathbb{C}^{mn\times mn}$ is an upper triangular block matrix and $L^{(n)}_1 \in \mathbb{C}^{nn\times nn}$ is a lower triangular block matrix. We denote $I_k^{(m,n)} = R^{(m)}_1 L^{(n)}_1$, which is the top-left $RL_m \times RL_n$ submatrix is block upper-triangular. By substitution of these expressions into (6) we obtain a coupled block SGSD scheme the goal is to minimize the following function:

$$\eta(\Omega) = \sum_{m,n=1}^{M} \sum_{l=1}^{K} \| Q^{(m)}(\omega) T^{(n)}(\omega) Z^{(n)} - F^{(m,n)}(\omega) \|^2.$$

Minimizing (8) is equivalent to minimizing the following:

$$\xi(Q^{(m)},...,Q^{(m)},Z^{(n)},...,Z^{(n)}) = \sum_{m,n=1}^{M} \sum_{l=1}^{K} \| Q^{(m)}(\omega) T^{(n)}(\omega) Z^{(n)} - F^{(m,n)}(\omega) \|^2,$$

where $\| \cdot \|_{F}$ denotes the Frobenius norm of the strictly block lower-triangular part. Note that (9) involves only unitary factor matrices, which are optimally conditioned. This has been achieved by relaxing the block-diagonal structure of $\Sigma^{(m,n)}$ in (6) to the block-upper-triangular structure of $\Gamma_k^{(m,n)}$ in (8).

When the coupled block SGSD is solved, algorithms will be presented later in subsections 3.2 and 3.3, and we will come up with the block-upper triangular matrices $\Gamma_k^{(m,n)}$. We recall that $I_k^{(m,n)} = R^{(m)}_1 L^{(n)}_1$, where $R^{(m)}_1 \in \mathbb{C}^{mn\times mn}$ and $L^{(n)}_1 \in \mathbb{C}^{nn\times nn}$ are the top-left block on the main diagonal of $\Gamma_k^{(m,n)}$, $\overline{R}^{(m)}_1 \in \mathbb{C}^{mn\times mn}$ and $\overline{L}^{(n)} \in \mathbb{C}^{nn\times nn}$, respectively. Note that $\overline{R}^{(m)}_1$ and $\overline{L}^{(n)}$ are invertible, and (10) implies that $\Gamma_k^{(m,n)}$ is an estimate of $\overline{C}^{(m,n)}$ up to trivial indeterminacies. We arrange $\Gamma_k^{(m,n)}$ into a matrix denoted as $C^{(m,n)} \in \mathbb{C}^{mn\times mn}$ in the same way that $C^{(m,n)}$ in (2) is obtained from $C^{(m,n)}$ in (2). According to (10) we have the following:

$$C^{(m,n)} = \begin{bmatrix} R^{(m)}_1 \otimes \overline{L}^{(n)}_1 \\ \vdots \\ \overline{R}^{(m)}_1 \otimes R^{(n)}_1 \end{bmatrix} \in \mathbb{C}^{mn\times mn}.$$
to minimize the strictly below block-diagonal norms of the second $L_n$ columns of $\mathbf{T}^{(2,k)}$ without affecting the first $L_n$ columns. This can be done by looking at a reduced problem where the same reasoning as in the calculation of $\mathbf{H}^{(2)}$ is followed for $\mathbf{T}^{(2,k)}$ with the first $L_n$ columns removed. After $\mathbf{H}^{(2)}$ is computed, the matrices $\mathbf{H}^{(3)}_{\alpha}, \ldots, \mathbf{H}^{(3)}_{\beta}$ follow sequentially. The update of $\mathbf{Z}^{(3)}$ is similar to $\mathbf{Q}^{(3)}$.

3.3. Jacobi Iteration

Here we alternate between updates of $\mathbf{Q}^{(m)}$ and $\mathbf{Z}^{(m)}$, each computed as the product of a sequence of elementary Givens matrices. For the update of $\mathbf{Q}^{(m)}$, in each step the matrices $\mathbf{Q}^{(m)}$ and $\Gamma^{(m)}_k$ are updated by a Givens matrix $\mathbf{G}_{uv} \in \mathbb{C}^{n \times n}$ as $\mathbf{Q}^{(m)} \leftarrow \mathbf{Q}^{(m)} \mathbf{G}_{uv} \mathbf{Q}^{(m)}$, $\Gamma^{(m)}_k \leftarrow \mathbf{G}_{uv} \Gamma^{(m)}_k \mathbf{G}_{uv}^T$, $1 \leq u < v \leq I_m$, where $\mathbf{G}_{uv}$ is equal to the identity matrix except $(\mathbf{G}_{uv})_{uv} = c_{uv}$, $(\mathbf{G}_{uv})_{vu} = s_{uv}$, $(\mathbf{G}_{uv})_{vw} = s_{uv}^*$, $(\mathbf{G}_{uv})_{uw} = c_{uv}^*$, with $c_{uv} \triangleq \cos \theta_{uv}$ and $s_{uv} \triangleq \sin \theta_{uv}$.

Denoting $\mathbf{\zeta} \triangleq \sum_k \mathbf{G}^{(m)}_k \mathbf{\Gamma}^{(m)}_k \mathbf{G}^{(m)}_k \in \mathbb{C}^{n \times n}$, the cost function (9) can be written as $\mathcal{E} = \sum_{n} \mathbf{\zeta}_{nn}$. Then for fixed $m$, an iteration step $(u,v)$ consists of finding $c_{uv}$ and $s_{uv}$ that minimize $\mathcal{E}$. Note that $\mathbf{G}_{uv}$ only affects the $u$th and $v$th rows of $\mathbf{\Gamma}^{(m)}_k$, and that the minimization of $\mathbf{\zeta}$ amounts to minimizing the strictly lower-block-triangular parts of the $n$th and $r$th columns of $\mathbf{G}^{(m)}_k \mathbf{\Gamma}^{(m)}_k$ for all values of $n$ and $k$.

With some technical derivations we obtain the following:

$$
\mathbf{M}_{uv}^{(m)} = \mathbf{w}_{uv}^{(m)} \bar{M}_{uv}^{(m)} \mathbf{w}_{uv}^{(m)},
$$

where $\bar{M}_{uv}^{(m)} \triangleq \sum_{k=1}^{M} (\mathbf{M}_{uv}^{(m)} + \mathbf{M}_{uv}^{(m)}^*) + 2 \text{Re}(\mathbf{M}_{uv}^{(m)}^*)$, and $\mathbf{w}_{uv}^{(m)} \triangleq [\text{Re}(\mathbf{M}_{uv}^{(m)}), \text{Im}(\mathbf{M}_{uv}^{(m)})]^T \in \mathbb{R}^2$, and $\mathbf{M}_{uv}^{(m)} \in \mathbb{C}^{n \times n}$ are defined as:

$$
\begin{bmatrix}
\mathbf{M}_{uv}^{(m)}_{11} & \mathbf{M}_{uv}^{(m)}_{12}
\end{bmatrix} =
\begin{bmatrix}
(\mathbf{\Gamma}^{(m)}_{uv})_{11} & (\mathbf{\Gamma}^{(m)}_{uv})_{12}
\end{bmatrix} =
\begin{bmatrix}
\mathbf{M}_{uv}^{(m)}_{11} & -i\mathbf{M}_{uv}^{(m)}_{12}
\end{bmatrix},
$$

with $r_1 = (\nu - 1)/L_n$, $r_2 = (\nu - 1)/L_n$. Then $\mathbf{w}_{uv}^{(m)}$ is taken equal to the left most significant eigenvector of $\mathbf{M}_{uv}^{(m)}$. In each iteration for the update of $\mathbf{Q}^{(m)}$, we find the optimal rotation angles $c_{uv}, s_{uv}$ from an EVD. The update of $\mathbf{Z}^{(m)}$ can be addressed similarly, and is not further discussed.

4. NUMERICAL RESULTS

The target tensors are constructed as:

$$
\mathbf{P}^{(m,n)} = \sigma c \| \mathbf{T}^{(m,n)} \|_\sigma + \sigma \mathbf{N}^{(m,n)} \| \mathbf{N}^{(m,n)} \|_\sigma ,
$$

where $\mathbf{N}^{(m,n)}$ is generated by (1) with the entries of $\mathbf{A}^{(m)} \in \mathbb{C}^{l \times l \times l}$, $\mathbf{C}^{(m)} \in \mathbb{C}^{l \times l \times l}$ and $\mathbf{N}^{(m,n)} \in \mathbb{C}^{l \times l \times l}$ randomly drawn from complex normal distributions, $m, n = 1, \ldots, M$. We set $M = 2, K = 200, K = 2, L_1 = L_2 = L_3 = L = 2, I_1 = I_2 = I_3 = I = 6$. The signal-to-noise ratio (SNR) is defined with the signal level $\sigma_s$ and noise level $\sigma_n$ as $\text{SNR} = 20 \log_{10} (\frac{\sigma_s}{\sigma_n})$.

The proposed coupled rank-$(L_m, L_n, \ldots)$ BTD algorithms based on the extended QZ and Jacobi iteration are denoted as CLLD-EQZ and CLLD-Jacobi, respectively. For comparison, we implement coupled rank-$(L_m, L_n, \ldots)$ BTD with structured data fusion (CLLD-SDF) [21]. We also include in the comparison the computation of rank-$(L_m, L_n, \ldots)$ BTD by alternating least squares (LLD-ALS, [2]) for each tensor separately. For CLLD-EQZ and CLLD-Jacobi we initialize with identity matrices. For CLLD-SDF, we also initialize with the results from CLLD-EQZ. For LLD-ALS, we initialize with randomly generated factor matrices. With the obtained estimates we can reconstruct a set of tensors by (1). The average relative fitting error $\varepsilon$ used to evaluate the performance is defined as:

$$
\varepsilon = \frac{\sum_{m,n} (\| \mathbf{P}^{(m,n)} - \mathbf{P}_{\text{est}}^{(m,n)} \|_\sigma) / (\| \mathbf{P}^{(m,n)} \|_\sigma)}{M} ,
$$

where $\mathbf{P}^{(m,n)}$ is the reconstructed tensor. For CLLD-EQZ, CLLD-Jacobi and LLD-ALS, we terminate the iteration when $|\varepsilon_{m,n} - \varepsilon_{m,n+1}| / \varepsilon_{m,n} \leq 10^{-4}$, where $\varepsilon_{m,n}$ and $\varepsilon_{m,n+1}$ denote the relative fitting errors in the current and previous iteration, respectively. For CLLD-SDF, we set the tolerance parameters TolFun and TolX in the ’SDF NLS’ function of Tensorlab [26] to 0.001 and 0.03, respectively. For each SNR value, we perform 200 independent runs of all the algorithms. The results of mean $\varepsilon$ and CPU time versus SNR are drawn in Fig. 3. We can see that the proposed algorithms provide more accurate estimates and higher computational efficiency than LLD-ALS for moderate to high SNR. CLLD-SDF gives the most accurate results, at a higher computational cost. This illustrates the interest of taking the coupling into account. It also shows that CLLD-EQZ and CLLD-Jacobi (i) provide good estimates for sufficiently high SNR and (ii) may be used as a low-cost initialization of the more expensive CLLD-SDF.

5. CONCLUSION

We have proposed two algorithms for the computation of a new coupled rank-$(L_m, L_n, \ldots)$ BTD problem. The proposed algorithms are based on a coupled block version of the SGSD scheme, and can be used for the particular multi-set data fusion problem of J-ISA. Numerical results have shown that the proposed algorithms have fast computation and good accuracy, which makes them useful tools as such. When high accuracy is desired, they may be used to initialize algorithms that minimize the block-diagonal criterion (6) instead of the block-triangular criterion (8).
