ABSTRACT

We introduce a new combination approach for the mixture of adaptive filters based on the set-membership filtering (SMF) framework. We perform SMF to combine the outputs of several parallel running adaptive algorithms and propose unconstrained, affinely constrained, and convexly constrained combination weight configurations. Here, we achieve better trade-off in terms of the transient and steady-state convergence performance while providing significant computational reduction. Hence, through the introduced approaches, we can greatly enhance the convergence performance of the constituent filters with a slight increase in the computational load. In this sense, our approaches are suitable for big data applications where the data should be processed in streams with highly efficient algorithms. In the numerical examples, we demonstrate the superior performance of the proposed approaches over the state of the art using the well known datasets in the machine learning literature.

Index Terms—Big Data, mixture approach, set-membership filtering, computational reduction

1. INTRODUCTION

Recently, the mixture approaches have been proposed to combine various adaptive filters with different configurations to achieve better performance than any of the individual algorithm in the mixture [1–6]. Particularly, through the mixture approach we can achieve enhanced performance in a wide range of adaptive filtering applications.

However, we emphasize that the mixture approaches multiplicatively increase the combination load, since they need to run several adaptive algorithms in parallel. Hence, these approaches may not be suitable for applications involving big data due to their impractical computational need.

To this end, in this paper, we introduce a new mixture approach based on set-membership filtering (SMF) framework introduced by Gollamudi et. al. [7] We developed unconstrained, affine and convex combination methods using SMF in order to reduce computational load and achieve improved performance in mixture approaches [8–10]. In the conventional least squares algorithms, e.g., the LMS algorithm (or the stochastic gradient descent algorithm), we minimize a cost function of the error term defined as the difference between the desired and the estimated signals. On contrary, the set membership filtering approach seeks to find any parameter yielding smaller error terms than a predefined bound. SMF approach achieves relatively fast convergence performance in addition to the reduced computational load since we do not update the parameter unless we obtain larger error than the bound [11, 12].

2. PROBLEM DESCRIPTION

Considering an on-line setting where only the current feature vector $x(t)$ at time $t \geq 1$ is available for modeling the corresponding data $d(t)$, our aim is to sequentially estimate $\hat{d}(t)$ such that $d(t) = f(x(t))$ and for the estimation, we use linear mixture of parallel adaptive filters.

In this structure, our system consists of two parts. In the first part we have $m$ adaptive filters running in parallel to estimate the desired signal $\hat{d}(t)$ as in Fig.1. Each filter with their parameter vector $w_i(t), i = 1, \cdots, m$ and the input vector $x(t)$ produces an estimate $\hat{d}_i(t) = x^T(t)w_i(t)$ and in next step we update their parameter vector according to their estimation error $e_i(t) \triangleq d(t) - \hat{d}_i(t)$.

In the second part of the system, we have the mixture stage. At this point, we obtain the final estimate of the system by linearly combining the estimates of the parallel adaptive filters as $\hat{d}(t) = w^T(t)y(t)$ where $y(t) = col\{\hat{d}_1(t), \cdots, \hat{d}_m(t)\}$ is constituent estimates vector and $w(t) = col\{w^{(1)}(t), \cdots, w^{(m)}(t)\}$ is mixture weights vector. Linear combination parameters of this stage are updated adaptively according to the final estimation error $e(t) \triangleq d(t) - \hat{d}(t)$.

Use of conventional least squares algorithms such as LMS algorithm in these mixture combination systems results in the update of parameter vectors of constituent filters at each step.

This work is in part supported by Turkish Academy of Science Outstanding Researcher Programme and TUBITAK Contract No: 113E517.

1Through this paper, bold lower case letters denote column vectors and bold upper case letter denote matrices. For a vector $\mathbf{a}$ (or matrix $\mathbf{A}$), $\mathbf{a}^T$ (or $\mathbf{A}^T$) is its ordinary transpose. The operator $\text{col}\{\cdots\}$ produces a column vector or a matrix in which the arguments of $\text{col}\{\cdots\}$ are stacked one under the other. For a given vector $\mathbf{w}$, $\mathbf{w}^{(i)}$ denotes the $i$th individual entry of $\mathbf{w}$. Similarly for a given matrix $\mathbf{G}$, $\mathbf{G}^{(i)}$ is the $i$th row of $\mathbf{G}$. For a vector argument, $\text{diag}\{\cdots\}$ creates a diagonal matrix whose diagonal entries are elements of the associated vector.
This notion may not be desirable for most big data applications due to high computational load that these updates will create. Therefore, as a solution, we employ set membership filters and their mixture combination for this structure.

In subsequent sections, we first introduce the structure of the SMF, then we introduce methods for linear mixture combination of these set membership filters.

3. STRUCTURE OF SET-MEMBERSHIP FILTERS

For the general linear-in-parameter filters whose input is \( x \in \mathbb{R}^n \), the desired output is real scalar \( d \) and the output of the filter is \( y = x^T w \) where \( w \in \mathbb{R}^n \) is the parameter vector for the filter. The filter error is defined as \( e(w) = d - y \). In a conventional least squares algorithm, filter estimates the parameter vector to minimize the cost which is a function of the filter error [13]. However, in the set membership filtering scheme, we update the parameter vector to satisfy a predefined upper bound \( \gamma \) on the filter error for all data pairs \((d, x)\) in a model space \( S \) such that \( |e(w)|^2 \leq \gamma \), \( \forall (d, x) \in S \). Therefore any parameter vector satisfying this condition is an acceptable solution and the set of these solutions forms the feasibility set which is defined as

\[
\Gamma = \bigcap_{(d, x) \in S} \{ w \in \mathbb{R}^n : |d - x^T w|^2 \leq \gamma^2 \}. \tag{1}
\]

If the model space \( S \) is known priori, then it is possible to estimate the feasibility set or a parameter vector in it. However, there is no closed form solution for an arbitrary \( S \) and in practice the model space is not known completely or it is time-varying [7]. Therefore we estimate the feasibility set or one of its members using set-membership adaptive recursive techniques (SMART).

Considering a practical case, where only measured data pair \((d_t, x_t)\) is available, the constraint set \( H_t \) containing all parameter vectors satisfying error bound condition is defined as \( H(t) = \{ w \in \mathbb{R}^n : |d(t) - w^T x(t)|^2 \leq \gamma \} \) and an estimate for the feasibility set at time \( t \) is membership set \( \phi_t = \bigcap_{\tau = 1}^t H(\tau) \). We approximate the membership set for tractable and computable results by projecting current parameter vector \( w(t) \) onto constraint set \( H(t + 1) \) if it is not contained in it and assure an error upper bound of \( \gamma \) [7].

We express the problem defined above as

\[
w(t + 1) = \arg \min_{w \in \mathbb{H}(t+1)} ||w - w(t)||^2. \tag{2}
\]

Solution to problem in (2) is

\[
w(t + 1) = w(t) + \mu(t) \frac{x(t)e(t)}{x^T(t)x(t)} \tag{3}
\]

where

\[
\mu(t) = \begin{cases} 1 - \frac{\gamma}{||e(t)||} & \text{if } ||e(t)|| > \gamma, \\ 0 & \text{otherwise}. \end{cases}
\]

The resulting algorithm in (3) is named as set membership normalized least mean square algorithm (SM-NLMS) and achieves better convergence speed and steady-state MSE with reduced computational load than NLMS algorithm [7]. In the next section, we use this SMF structure in constituent and combination filters of mixture combination approach to create computationally efficient and fast converging estimation system.

4. PROPOSED COMBINATION METHODS

We employ SMF scheme for the mixture combination of constituent set-membership filters with different error bounds running in parallel to estimate the desired signal \( d(t) \). We use a system where \( m \) SMF filter running in parallel as in Fig.1, each one updates their parameter vector \( w_i(t) \in \mathbb{R}^n \) and produces estimate \( \hat{d}_i(t) = x^T(t)w_i(t) \) with respect to its bound \( \gamma_i \). In the combination stage of \( m \) constituent filters, we combine each filter output linearly through time variant weight vector \( w(t)^{(i)} \in \mathbb{R}^m \) which is trained with combining SMF filter with bound \( \bar{\gamma} \). We denote input to the combination stage as \( y(t) = [\hat{d}_1(t), ..., \hat{d}_m(t)] \) and the parameter vector of the combination stage is \( w(t) = [w^{(1)}(t), ..., w^{(m)}(t)] \). The output of the combination stage is \( \tilde{d}(t) = y^T(t)w(t) \) and the final estimation error is \( e(t) = \tilde{d}(t) - d(t) \).

In the following subsections, we seek and train parameter vectors for the combination stage weights satisfying upper bound \( \bar{\gamma} \) within different parameter spaces.

4.1. Unconstrained Linear Mixture Parameters

The first parameter space is for the unconstrained linear mixture weights and defined as \( W_1 \equiv \{ w \in \mathbb{R}^n \} \) which is the Euclidean space. Therefore, within the SMF scheme, for finding and update of the weights we have

\[
w(t + 1) = \arg \min_{w \in W_1(t)} ||w - w(t)||^2 \tag{4}
\]

where \( W_1(t) = \{ w \in W_1 : |d(t) - w^T y(t)| \leq \bar{\gamma} \} \) is the constraint set for the update and the solution for the (4) as we did in (2) yields

\[
w(t + 1) = w(t) + \mu(t) \frac{y(t)e(t)}{y^T(t)y(t)} \tag{5}
\]

where

\[
\mu(t) = \begin{cases} 1 - \frac{\bar{\gamma}}{||e(t)||} & \text{if } ||e(t)|| > \bar{\gamma}, \\ 0 & \text{otherwise}. \end{cases}
\]

4.2. Affine Mixture Parameters

Parameter space for the affine mixture weights is defined as \( W_2 \equiv \{ w \in \mathbb{R}^n : \mathbf{1}^T w = 1 \} \) where \( \mathbf{1} \in \mathbb{R}^n \) denotes...
a vector of ones such that sum of weights to be one, i.e. \( \sum_{i=1}^{m-1} w(i) = 1 \). Therefore, the constraint set in this case is \( \mathcal{H}_2(t) = \{ w \in \mathcal{W}_2 : d(t) - \text{w}^T \text{y}(t) \leq \gamma \} \). We remove the affine constraint with the following parametrization. Define parameter vector \( z(t) \in \mathbb{R}^{m-1} \) where

\[
z(i)(t) \triangleq w(i)(t), \quad \forall i \in \{1, 2, ..., m-1\}
\]

and

\[
w^{(m)}(t) = 1 - \sum_{i=1}^{m-1} z(i)(t)
\]

(6)

Here in (6) we present \( z(t) \) as the unconstrained parameter vector and define \( a(t) \) as the desired signal and \( c(t) \) as the input to the unconstrained optimization problem which is given as

\[
z(t+1) = \arg \min_{z \in \mathcal{H}_2(t)} ||z - z(t)||^2,
\]

(7)

where the constraint set is defined as \( \mathcal{H}_2(t) = \{ z \in \mathbb{R}^{m-1} : |a(t) - z^T c(t)| \leq \gamma \} \) and we can express

\[
a(t) = d(t) - \hat{d}_m(t); \quad c(t) = \begin{bmatrix} \hat{d}_1(t) - \hat{d}_m(t) \\ \vdots \\ \hat{d}_{m-1}(t) - \hat{d}_m(t) \end{bmatrix}
\]

Since now the optimization problem is same as in unconstrained case, as in (4) the solution yields

\[
z(t+1) = z(t) + \mu(t) \frac{c(t)e(t)}{c(t)^T c(t)}
\]

(8)

where

\[
\mu(t) = \begin{cases} 1 - \frac{\gamma}{|e(t)|} & \text{if } |e(t)| > \gamma, \\ 0 & \text{otherwise.} \end{cases}
\]

Therefore with the relation in (6), we can write for \( \mathcal{W}_2 \) space that

\[
w(t+1) = w(t) + \mu(t) \frac{Gy(t)e(t)}{y(t)^T Gy(t)}
\]

(9)

where

\[
G \triangleq \begin{bmatrix} I_{m-1} & -1 \\ -I_{m-1} & m - 1 \end{bmatrix}
\]

and

\[
\mu(t) = \begin{cases} 1 - \frac{\gamma}{|e(t)|} & \text{if } |e(t)| > \gamma, \\ 0 & \text{otherwise.} \end{cases}
\]

and \(-1 \in \mathbb{R}^{m-1}\) is a vector where all its elements is minus one.

4.3. Convex Mixture Parameters

Finally, the parameter space for the convex mixture weights is defined as \( \mathcal{W}_3 = \{ w \in \mathbb{R}^m : 1^T w = 1 \land w(i) \geq 0, \forall i \in \{1, ..., m\} \} \). In order to get unconstrained optimization problem as we did above, we re-parameterize vector \( w(t) \) with the parameter vector \( z(t) \in \mathbb{R}^{m} \) as in [8]

\[
w(i)(t) = \frac{e^{-z(i)(t)}}{\sum_{k=1}^{m} e^{-z(k)(t)}}.
\]

Note that SM-NLMS algorithm also could be constructed through gradient descent method with stochastic cost function defined as

\[
F(e(t)) \triangleq \begin{cases} \left( \frac{|e(t)| - \gamma}{|e(t)|} \right)^2 & |e(t)| > \gamma, \\ 0 & \text{otherwise.} \end{cases}
\]

Therefore, for the unconstrained parameter vector update, stochastic gradient algorithm is given by

\[
z(t+1) = z(t) - \frac{1}{2} \nabla F(e(t))
\]

(11)

which by chain rule yields to

\[
z(t+1) = z(t) - \frac{1}{2} \nabla F(e(t))
\]

(12)

Note that \( \nabla F(e(t)) = w(t)w(t)^T - \text{diag}\{w(t)\} \) [8] and by this we obtain

\[
z(t+1) = z(t) + \mu(t) \frac{y(t)e(t)}{y(t)^T y(t) - \text{diag}\{w(t)\}}
\]

(13)

where

\[
\mu(t) = \begin{cases} 1 - \frac{\gamma}{|e(t)|} & \text{if } |e(t)| > \gamma, \\ 0 & \text{otherwise.} \end{cases}
\]

and

\[
w(t) = \frac{e^{-z(t)}}{||e^{-z(t)}||}. \]

With the algorithms defined above, in next section we evaluate the MSE performance of the algorithms within different schemes.

5. SIMULATIONS AND RESULTS

In this section, through wide range of benchmark real life datasets and simulations, we demonstrate the performance of the proposed SMF filter mixture algorithms and compare the steady-state and convergence performances with various methods, i.e. NLMS, variable step size NLMS (VSS) and affine projection algorithm (APA), as well as its superior computational efficiency [13, 14].

5.1. Stationary Data

In this part, we study our algorithms in a stationary environment where data source statistics do not change over time. We use input vectors with eigenvalue spread of 1 and 0 dB SNR signal, where \( \sigma_n^2 \) represents the white Gaussian noise variance. Parameter of interest chosen randomly from normal distribution and normalized to \( ||w_n|| = 1 \). We use 10 constituent SM-NLMS filters with different error bounds set around \( \sqrt{\sigma_n^2} \). For comparison, we used NLMS mixture algorithm and a single NLMS algorithm with step size \( \mu_{NLMS} = 0.2 \), VSS-NLMS algorithm with step size range \( (\mu_{max}, \mu_{min}) = (0.2, 0.02) \) and APA algorithm of order 5. In Fig.2, we demonstrate the time accumulated regression errors averaged over 100 independent trials. We observe that SMF and NLMS mixture of set membership filters outperform other filters (NLMS, VSS-NLMS and APA) in both convergence rate and residual error sense. Also, note that SMF mixture algorithms achieve better steady state error than the NLMS mixture algorithm.
5.2. Benchmark Real Data
Finally, we apply our algorithms to the regression of the benchmark real-life problems [15]. In real-life dataset experiments, we use 10 constituent SMF filters and since this time we do not know the power of the additive noise, we set the error bounds of the SMF filters in a wide range spread around 0.15 and again we choose the error bound for the combinator SMF filter as 0.15. We make 100 trials over a dataset by shuffling the data at each trial.

We use Elevator data with regressor dimension 18 which is a dataset obtained from the task of controlling F16 aircraft and the desired data is related to an action taken on the elevators of the aircraft [15]. We set the order of APA algorithm as 8 for this case. We present the results for this dataset in Fig.3. Note that in Fig.3, mixture approaches show superior performance over other filters. Although APA algorithm shows a close performance to mixture filters, we emphasize that APA algorithm is computationally inefficient for big data applications compared to proposed methods since it requires memory for holding old data at its order and require more multiplication and addition operations at each update. We present detailed results for that in the computational load analysis part.

5.3. Computational Load
One of the critical aspects of the proposed algorithms is the reduced computational load regarding lessened update of weights compared to the standard NLMS algorithms and mixture methods. To present that, we calculated the total number of addition and multiplication operation that each algorithm made during the simulation. In Fig.4, we demonstrate results for addition and multiplication operation that each algorithm made in 100 independent experiment over stationary data and show that proposed algorithms computationally more efficient than other algorithms. Although, the computational cost among the proposed algorithms do not differ much, we emphasize that the unconstrained mixture is the most computationally efficient one. We note that SMF mixture algorithms provide computational efficiency up to order of magnitude of 3.

6. CONCLUSION
In this paper we introduced a novel mixture of expert algorithm in order to reduce the computational demand of the mixture approaches. Since the ordinary mixture approaches require to run several adaptive filters in parallel, they are impractical in applications involving big data due to complexity issues. To this end, by using the SMF, we significantly reduced the computational complexity of these approaches while providing superior performance. We provided unconstrained, affine and convex mixture weight configurations using set membership filtering framework. Through numerical experiments in stationary environments and through regression of a benchmark real life problem, we investigated the steady-state mean square error and convergence rate performance of these algorithms compared with other algorithms and mixture methods. In these experiments we demonstrated that proposed algorithms reach faster convergence rate and lower steady state error. Finally, we showed that our set membership filtering based approaches requires less addition and multiplication operations hence less computational load than the compared algorithms.
